## 5 Performance Evaluation [45 points]

A multi-cycle processor P1 executes load instructions in 6 cycles, store instructions in 6 cycles, arithmetic instructions in 2 cycles, and branch instructions in 2 cycles. Consider an application A where 40% of all instructions are load instructions, 20% of all instructions are store instructions, 30% of all instructions are arithmetic instructions, and 10% of all instructions are branch instructions.

(a) [10 points] What is the CPI of application A when executing on processor P1? Show your work.

$$CPI = 0.4 \times 6 + 0.2 \times 6 + 0.3 \times 2 + 0.1 \times 2$$
  
 $CPI = 4.4$ 

(b) [10 points] A new design of the processor doubles the clock frequency of P1. However, the latencies of all instructions increase by 4 cycles. We call this new processor P2. The compiler used to generate instructions for P2 is the same as for P1. Thus, it produces the same number of instructions for program A. What is the CPI of application A when executing on processor P2? Show your work.

$$CPI = 0.4 \times 10 + 0.2 \times 10 + 0.3 \times 6 + 0.1 \times 6$$
  
 $CPI = 8.4$ 

(c) [5 points] Which processor is faster (P1 or P2)? By how much (i.e., what is the speedup)? Show your work.

```
P2 is 1.05 \times faster than P1.
Explanation.
Execution Time P1 = instructions \times CPI_{P1} \times clock time
Execution Time P2 = instructions \times CPI_{P2} \times \frac{clock\_time}{2}
clock\_time = \tfrac{1}{clock\_frequency}
Assuming that Execution\_Time\_P2 < Execution\_Time\_P1 \frac{Execution\_Time\_P1}{Execution\_Time\_P2} > 1. Thus:
       \underline{instructions} \times CPI_{P1} \times clock\_time
        instructions \times CPI_{P2} \times \frac{clock\_time}{2}
        \frac{4.4 \times clock\_time}{8.4 \times \frac{clock\_time}{2}}
       1.05
```

- (d) [20 points] You want to improve the original P1 design by including one new optimization without changing the clock frequency. You can choose only one of the following options:
  - (1) ALU: An optimized ALU, which halves the latency of both arithmetic and branch instructions.
  - (2) LSU: An asymmetric load-store unit, which halves the latency of load operations but doubles the latency of store operations.

Which optimization do you add to P1 for application A? Show your work and justify your choice.

The ALU optimization.

## Explanation.

Application A executes 40% load, 20% store, 30% arithmetic, and 10% branch instructions.

By Amdahl's Law, we have:

$$\begin{split} Speedup_{ALU} &= \frac{1}{(1-0.3-0.1)+\frac{0.3+0.1}{2}} = 1.25 \\ Speedup_{LSU} &= \frac{1}{(1-0.4-0.2)+\frac{0.4}{2}+0.2\times 2} = 1.0 \end{split}$$

The ALU optimization provides 1.25× speedup, while the LSU provides no speedup at all.

## Alternative Solution.

With the ALU, the new CPI of processor P1 will be:  $CPI_{ALU} = 0.4 \times 6 + 0.2 \times 6 + 0.3 \times \frac{2}{2} + 0.1 \times \frac{2}{2}$  $CPI_{ALU} = 4.0$ 

With the LSU, the new CPI of processor P1 will be:  $CPI_{LSU} = 0.4 \times \frac{6}{2} + 0.2 \times (6 \times 2) + 0.3 \times 2 + 0.1 \times 2$ 

Since  $CPI_{ALU}$  <  $CPI_{LSU}$ , integrating the ALU will improve the overall cyclesper-instructions.
