type instruction and JReg depends on the function field only. When JReg is equal to '1', PCSrc (PC control unit output control signal) will be '10' to select the value of register Rs as input to PC.

Also, we need to store PC+4 in register Rd. To accomplish this, we need another multiplexer to select between the incremented PC, the ALU result and data memory out, to be placed on BusW. Also, we need to add a path from the output of the incremented PC to the input of this new multiplexer. A control signal 'RA' (Return Address) is needed to select between the incremented PC and the ALU result. The MemtoReg multiplexer selects between the output of the 'RA' multiplexer and the Data Memory output to place on BusW.

b) Show the values of the control signals to control the execution of the **jalr** instruction. If you need add a new control signal, please add it along with its value to the table below. Use the following table for ALUCtrl.

Al II function	4-hit Al II Control				
AND	0001				
∩R	0010				
XOR	0011				
ADD	0100				
SUR	0101				
SLT	0110				

The main control signals for the JALR instruction are the same for other R-type instructions, such as ADD and SUB. The ALU Control signals for the JALR instruction require JReg = 1, RA = 0 and ALUCtrl is a don't care. These control signals are shown in the table below:

RegDs	RegWrit	Ext0	ALUST	MemRead	MemWrite	MemtoReg	ALUCtr	J	Be	Bn	R	JRe
t	е	P	c				1		q	e	A	g
Rd =	1	X	X	0	0	0	XXXX	0	0	0	0	1
1												

Q2. Processor Performance

Suppose we add the multiply and divide instructions. The operation times are as follows:

Instruction memory access time = 190 ps,
Register file read access time = 150 ps,
ALU delay for basic instructions = 190 ps,
Ignore the other delays in the multiplexers, control unit, sign-extension, etc.

Assume the following instruction mix: 30% ALU, 15% multiply & divide, 20% load, 10% store, 15% branch, and 10% jump.

a) What is the total delay for each instruction class and the clock cycle for the single-cycle CPU design?

Instruction Class	Instruction Memory	Register Read	ALU Data Memory		Register Write	Total Delay	
Basic ALU	190 ps	150 ps	190 ps		150 ps	680 ps	
Mul & Div	190 ps	150 ps	550 ps		150 ps	1040 ps	
Load	190 ps	150 ps	190 ps	190 ps	150 ps	870 ps	
Store	190 ps	150 ps	190 ps	190 ps		720 ps	
Branch	190 ps	150 ps	190 ps			530 ps	
Jump	190 ps	150 ps				340 ps	

```
Clock cycle = max delay = 1040 ps.
```

b) Assume we fix the clock cycle to 200 ps for a multi-cycle CPU, what is the CPI for each instruction class and the speedup over a fixed-length clock cycle?

```
Solution:
```

```
CPI for Basic ALU = 4 cycles

CPI for Multiply & Divide = 6 cycles

CPI for Load = 5 cycles

CPI for Store = 4 cycles

CPI for Branch = 3 cycles

CPI for Jump = 2 cycles

Average CPI = 0.3 * 4 + 0.15 * 6 + 0.2* 5 + 0.1 * 4 + 0.15 * 3 + 0.1 * 2 = 4.15

Speedup of multi-cycle over single-cycle = (1040 * 1) / (200 * 4.15) = 1.253
```

Q3. (10 pts) Consider the following MIPS code sequence:

```
a: add $t0, $s0, $s1b: sub $t1, $s2, $t0c: xor $t0, $s0, $s1d: or $t2, $t1, $t0
```

a) (5 pts) Identify all the RAW dependencies between pairs of instructions.

```
Instruction b is dependent on instruction a ($t0) Instruction d is dependent on instruction b ($t1) Instruction d is dependent on instruction c ($t0)
```
